

A Guide to the Java UR

Last modified February 12, 2020

by baeldun(<https://www.baeldung.com/author/baeldung>)

Java(<https://www.baeldung.com/category/java>) +

I just announced the new *Learn Spring* course, focused on the fundamentals of Spring 5 and Spring Boot 2:

>> CHECK OUT THE COURSE ([/ls-course-st](#))

1. Overview

In this article, we are going to explore low-level operations with Java network programming. **We'll be taking a deeper look at URLs.**

A URL is a reference or an address to a resource on the network. And simply put, Java code communicating over the network can use the `java.net.URL` class to represent the addresses of resources.

The Java platform ships with built-in networking support, bundled in the `java.net` package.

```
1 import java.net.*;
```

2. Creating a URL

Let's first create a `java.net.URL` object by using its constructor and passing in a String representing the human-readable address of the resource.

```
1 URL url = new URL("/a-guide-to-java-sockets");
```

We use cookies to improve your experience with the site. To find out more, you can read the full [Privacy and Cookie Policy \(/privacy-policy\)](#). We've just created an **absolute URL object**. The address has all the parts required to reach the desired resource.

We can also create a **relative URL**, assuming we have the URL object representing the home page of the application.

```
1 URL home =new URL("http://baeldung.co");
```

Next, let's create a new URL pointing to a resource we already know; we're going to use another constructor, the existing URL and a resource name relative to that

```
1 URL url =new URL(home,"a-guide-to-java-socket");
```

We have now created a new URL *url* relative to *home*; so the relative URL is only valid within the context of the URL.

We can see this in a test

```
1 @Test
2 public void givenBaseUrl_whenCreatesRelativeUrl_thenCorrect() {
3     URL baseUrl =new URL("http://baeldung.co");
4     URL relativeUrl =new URL(baseUrl,"a-guide-to-java-socket");
5
6     assertEquals("http://baeldung.com/a-guide-to-java-socket",
7         relativeUrl.toString())
8 }
```

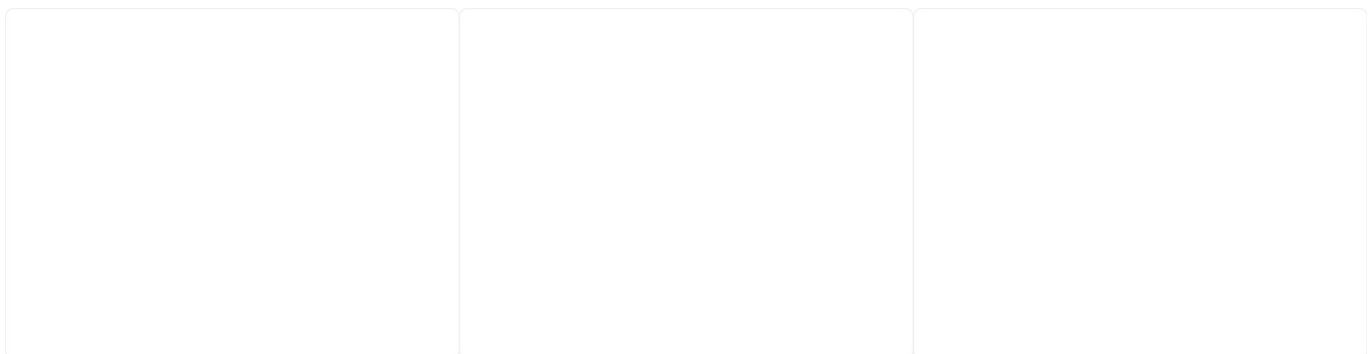

However if the relative URL is detected to be absolute in its component parts *baseUrl* is ignored

```
1 @Test
2 public void givenAbsoluteUrl_whenIgnoresBaseUrl_thenCorrect() {
3     URL baseUrl =new URL("http://baeldung.co");
4     URL relativeUrl =new URL(
5         baseUrl,"/a-guide-to-java-socket");
6
7     assertEquals("http://baeldung.com/a-guide-to-java-socket",
8         relativeUrl.toString())
9 }
```

Finally, we can create a URL by calling another constructor which takes in the component parts of the URL. We cover this in the next section after covering URL components.

3. URL Component

A URL is made up of a few components – which we'll explore in this section.

Let's first look at the separation between the protocol identifier and the resource – these two components are separated by a colon followed by two forward slashes://.

If we have a URL such as *http://baeldung.co* then the part before the separator *http* is the protocol identifier while the part that follows is the resource name *baeldung.co*.

Let's have a look at the API that *URL* objects expose.

We use cookies to improve your experience with the site. To find out more, you can read the full [Privacy and Cookie Policy \(/privacy-policy\)](#)

Ok

3.1. The Protocol

To retrieve **the protocol** – we use the `getProtocol()` method

```
1 @Test
2 public void givenUrl_whenCanIdentifyProtocol_thenCorrect(){
3     URL url =new URL("http://baeldung.co");
4
5     assertEquals("http", url.getProtocol())
6 }
```

3.2. The Port

To get **the port** – we use the `getPort()` method

```
1 @Test
2 public void givenUrl_whenGetsDefaultPort_thenCorrect(){
3     URL url =new URL("http://baeldung.co");
4
5     assertEquals(1, url.getPort())
6     assertEquals(80, url.getDefaultPort())
7 }
```

Note that this method retrieves the explicitly defined port. If no port is defined explicitly, it will

And because HTTP communication uses port 80 by default – no port is

Here's an example where we do have an explicitly defined

```
1 @Test
2 public void givenUrl_whenGetsPort_thenCorrect(){
3     URL url =new URL("http://baeldung.com:809");
4
5     assertEquals(8090, url.getPort())
6 }
```

3.3. The Host

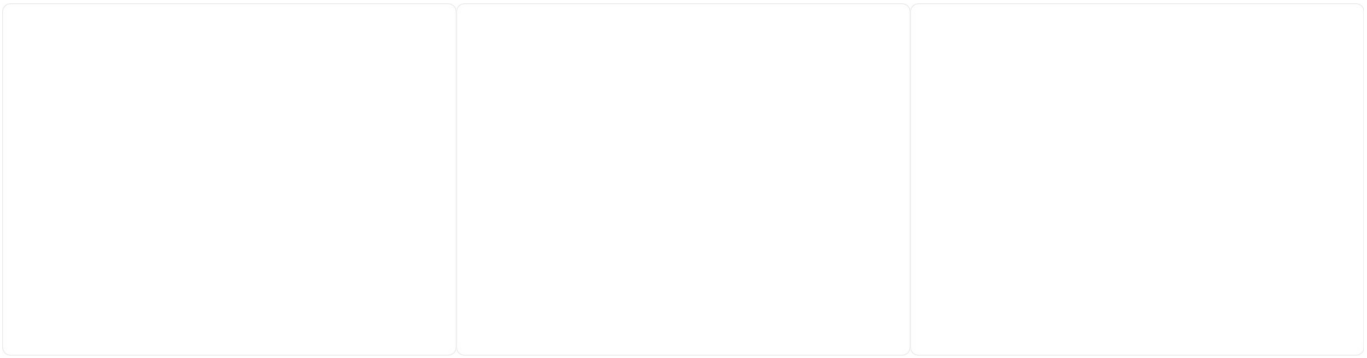

The host is the part of the resource name that starts right after the separator and ends with the domain name extension or case.

We call the `getHost()` method to retrieve the host:

```
1 @Test
2 public void givenUrl_whenCanGetHost_thenCorrect(){
3     URL url =new URL("http://baeldung.co");
4
5     assertEquals("baeldung.com", url.getHost())
6 }
```

3.4. The File Name

Whatever follows after the hostname in a URL is referred to as **the file name of the resource**. It can include both path and query parameters or just a file name.

```

1  @Test
2  public void givenUrl_whenCanGetFileName_thenCorre() {
3      URL url =new URL("http://baeldung.com/guidelines.");
4
5      assertEquals("/guidelines.txt", url.getFile())
6  }

```

Assuming Baeldung has java 8 articles under the `/articles?topic=java&version=8`. Everything after the hostname is file name

```

1  @Test
2  public void givenUrl_whenCanGetFileName_thenCorre() {
3      URL url =new URL("http://baeldung.com/articles?topic=java&version=8");
4
5      assertEquals("/articles?topic=java&version=8", url.getFile())
6  }

```

3.5. Path Parameter

We can also only inspect the **path** parameters which in our case `/article`

```

1  @Test
2  public void givenUrl_whenCanGetPathParams_thenCorr() {
3      URL url =new URL("http://baeldung.com/articles?topic=java&version=8");
4
5      assertEquals("/articles", url.getPath())
6  }

```

3.6. Query Parameter

Likewise, we can inspect the **query** parameter which is `topic=java&version=8`

```

1  @Test
2  public void givenUrl_whenCanGetQueryParams_thenCorr() {
3      URL url =new URL("http://baeldung.com/articles?topic=java<em>&version=8");
4
5      assertEquals("topic=java<em>&version=8", url.getQuery())
6  }

```

4. Creating URL With Component Pair

We use cookies to improve your experience with the site. To find out more, you can read the full [Privacy and Cookie Policy \(/privacy-policy\)](#). Since we have now looked at the different URL components and their place in forming the complete address to a resource, we can look at another method of creating a URL object by passing in the components individually.

The first constructor takes the protocol, the hostname and the file name re

```
1 @Test
2 public void givenUrlComponents_whenConstructsCompleteUrl_thenCor() {
3     String protocol = "http";
4     String host = "baeldung.com";
5     String file = "/guidelines.txt";
6     URL url = new URL(protocol, host, file
7
8     assertEquals("http://baeldung.com/guidelines.", url.toString())
9 }
```

Keep in mind the meaning of filename in this context, the following test should make

```
1 @Test
2 public void givenUrlComponents_whenConstructsCompleteUrl_thenCor() {
3     String protocol = "http";
4     String host = "baeldung.com";
5     String file = "/articles?topic=java&version";
6     URL url = new URL(protocol, host, file
7
8     assertEquals("http://baeldung.com/articles?topic=java&version", url.toString())
9 }
```

The second constructor takes the protocol, the hostname, the port number and the filename

```
1 @Test
2 public void givenUrlComponentsWithPort_whenConstructsComplete
3     thenCorrect() {
4     String protocol = "http";
5     String host = "baeldung.com";
6     int port = 9000;
7     String file = "/guidelines.txt";
8     URL url = new URL(protocol, host, port, file
9
10     assertEquals
11         ("http://baeldung.com:9000/guidelines.", url.toString())
12 }
```

5. Conclusion

In this tutorial, we covered the `URL` class and showed how to use it in Java to access network resources programmatically.

As always, the full source code for the article and all code snippets can be found on my [GitHub project](https://github.com/eugenp/tutorials/tree/master/core-java-modules/core-java-8) (<https://github.com/eugenp/tutorials/tree/master/core-java-modules/core-java-8>).
